AN APPROXIMATE CALCULATION OF ENERGY DISSIPATION AND ELECTRIC EROSION OF ELECTRODES IN THE HIGH-VOLTAGE HIGH-CURRENT AIR SWITCH OF ATMOSPHERIC PRESSURE

Purpose. To obtain new calculation correlations, determining approximate energy dissipation and electric erosion of massive basic metallic electrodes in the high-voltage high-current air switchboard (HVCAS) of atmospheric pressure, in-use in the bit chain of the high-voltage electrophysics setting (HVES) with the powerful capacity store of energy (CSE). Methodology. Electrophysics bases of technique of high-voltage and large impulsive currents (LIC), scientific and technical bases of development and planning of high-voltage heavy-current impulsive electro-devices, including HVES and powerful CSE, and also methods of measuring in their bit chains of LIC of the microsecond temporal range. Results. On the basis of new engineering approach the results of calculation estimation of excretions energy and electric erosion of massive basic metallic electrodes are resulted in probed HVCAS. New correlations are obtained for the approximate calculation of thermal energy, selected in an impulsive air spark and on the workings surfaces of anode and cathode of HVCAS. It is entered and a new electrophysics concept, touching equivalent active resistance of impulsive air spark, is mathematically certain. New formulas are obtained for the approximate calculation of most depth of single round crater of destruction on the workings surfaces of basic metallic electrodes of HVCAS, and also mass of metal, thrown out magnetic pressure from this crater of destruction on the electrodes of switch for one electric discharge through them powerful CSE HVES. It is shown that the radius of the indicated single crater of destruction is approximately equal to the maximal radius of plasma channel of a spark discharge between a cathode and anode of HVCAS. The executed high-current experiments in the bit chain of HVES with powerful CSE validated row of the got and in-use calculation correlations for the estimation of energy dissipation and electric erosion of metallic electrodes in examined HVCAS. Originality. New engineering approach is developed for the approximate calculation and estimation of energy dissipation and electric erosion of basic metallic electrodes in HVCAS. A formula is firstly got for approximate calculation unchanging in the process of swaying or aperiodic discharge of CSE HVES on the electric loading of active resistance of impulsive air spark between the electrodes of probed HVCAS. Practical value. Drawing on the got results in a high-voltage impulsive technique provides operative implementation of calculation of balance of electric energy in the high-current circuit of HVES with powerful CSE and point electric load, and also prognostication of the technical state of workings surfaces of massive basic metallic electrodes of HVCAS. References 21, figures 3.

Key words: high-voltage high-current air switch, dissipated thermal energy in air spark and on the electrodes of switch, electric erosion of metallic electrodes of switch, depth of single crater of destruction on the electrodes of switch, thrown out mass of metal from the single crater of destruction of electrodes of switch.

Introduction. It is known that the commutation of the accumulated electric energy in a high-capacity capacitive energy storage (CES) device of a high-voltage electrophysical setting (HVES) is performed by means of a special electrical engineering device termed arrester by domestic terminology, and by foreign terminology by a switch [1, 2]. In the future, let us dwell
on the latest technical term, which has become most widely used in modern high-voltage pulse technology (HVPT). Vacuum, various gases and their mixtures, liquids and solids can be used as working dielectric media of the considered HVES discharge circuit switches with powerful CSE [1-4]. A wide application in the field of modern HVPT because of its comparative cheapness and simplicity in manufacturing has received high-voltage high-current air switches (HVCAS) of atmospheric pressure at a constant voltage up to ±125 kV and commutated pulse currents up to ±1 MA amplitude [1, 5-7]. As a rule, the main electrodes of HVCAS are made of medium and refractory metals (for example, steel and molybdenum) or metal compositions (for example, «tungsten-copper» compositions) [1, 3-7]. One of the drawbacks of these HVCAS is the increased electroerosive wear of the working surfaces of their main metal electrodes, caused by the intense exposure of the high-power heat flux of the plasma channel of the spark discharge in the areas of its binding at the electrodes of such switches. In this connection, for HVCAS, the actual tasks are those related to the calculation estimation in such high-current heat loss in switches in the plasma spark channel and on the main electrodes of the HVCAS, as well as the electrical erosion of the working surfaces of their main metal electrodes.

The goal of the paper is obtaining new calculation relationships that determine in an approximate form the energy dissipation and electrical erosion of massive metal main electrodes in the HVCAS used in the discharge circuits of a number of HVES with the CSE.

### 1. Research objective definition.

Let us consider the HVES discharge circuit with a powerful CSE and an actively inductive load, switching large impulse current (LIC) in which the HVCAS performs with massive uniform base metal electrodes of a hemispherical shape-the cathode and the anode (Fig. 1). We suppose that these electrodes of HVCAS located in atmospheric air under normal conditions (air pressure is 1.013·10⁵ Pa and its temperature is equal to \( T_0 = 0 \) °C [8]) at the distance \( l_w \) from each other form a two-electrode system (TES). Let the radius \( R_c \) of the working surfaces of the cathode and the anode of the considered HVCAS exceeds the penetration depths in their conductive materials of the electromagnetic and thermal fields created by a cylindrical channel of a spark discharge of radius \( r_c < R_c \) in the areas of its binding on the working surfaces of the electrodes of the investigated HVCAS.

![Fig. 1. The principal electrical circuit of the HVES discharge circuit with a powerful CSE and a high-voltage high-current two-electrode air switch (1, 2 – massive metal cathode and anode of HVCAS of hemispherical shape with an outer radius \( R_c \); 3 – plasma high-current channel of an air spark discharge with length \( l_c \) and maximum radius \( r_{pm} \); \( R_g, L_g, C_g \) – the own electrical parameters of the HVES with CSE; \( R_l, L_l \) – the own electrical parameters of the active-inductive load; IIK – the measuring coaxial \( IIK-300 \) shunt designed to measure a microsecond pulse current with an amplitude of \( I_m \) up to ±300 kA with its action integral \( I_m \) up to 2.5·10⁶ J/Ω [9, 10])](image.png)

In this connection we assume that the working surfaces of these electrodes of the HVCAS of the high-current spark in the zones of fastening of the high-current spark in the first approximation will be close to flat. We assume that in the TES of the switchboard, the length \( l_c \) of the plasma spark channel is equal to the minimum length \( l_w \) of the interelectrode gap in the HVCAS. We assume that the heat flux density \( g_c(t) \) and the density \( \delta_d(t) \) of the discharge current \( i_d(t) \) of the HVES with CSE in the cylindrical spark discharge channel for the investigated HVCAS are practically uniformly distributed over its transverse circular cross section with a time-varying in \( t \) radius \( r_c \). One of the confirmations to this can be the fact that in a high-current plasma channel of a gas discharge thermodynamic electron and ion temperatures are characterized by a practically uniform distribution in its current radius \( r_c \) [11]. We use the assumption that the holes (craters) of failure appearing in the areas of binding of the plasma channel of the spark discharge on the working surfaces of the anode and the cathode of the HVCAS have a geometric shape close to the shape of the spherical segment [12, 13]. It is required, within the proposed engineering approach, to obtain new relationships for the approximate calculation of the energy release and electrical erosion of massive metal electrodes in the HVCAS of the HVES discharge circuit with powerful CSE, and also to perform in a high-voltage laboratory using a powerful capacitor-type generator that generates, on the \( RL \)-load, a microsecond range, experimental verification of the performance of some of these relationships.
2. Approximate calculation of the energy dissipation in the HVCAS of the discharge circuit of the HVES with CSE. First, let us dwell on the estimated evaluation of the thermal energy $W_c$, which is dissipated directly in the plasma channel of the air spark discharge, which arises between the metal electrodes of the HVCAS.

Proceeding from the known positions of electro- and thermophysics, the expression for $W_c$ can be represented in the following form:

$$W_c = R_c J_d,$$  
where $J_d = \int_0^\infty i(t)dt$ is the action integral of the pulsed current $i_d(t)$ in the discharge circuit of the HVES with CSE; $R_c$ is the equivalent active resistance of the plasma channel of the air spark in the switch.

Next, let us determine the calculation in (1) of the action integral $J_d$ of the current flowing in the HVES discharge circuit with CSE through the investigated HVCAS. In the case of a change in the current $i_d(t)$ according to the law of an exponentially damped sinusoid, which has the analytical form $i_d(t) = k_d J_m \exp(-\delta t) \sin(\omega t)$, the following calculation relation can be used for the action integral $J_d$ of the discharge current in the HVES circuit with a powerful CSE:

$$J_d = 0.25 k_d J_m \delta^{-1} \left[ \left( \delta / \omega \right)^2 + 1 \right]^{-1},$$  
where $J_m$ is the first amplitude of the discharge circuit $i_d(t)$ changing with angular frequency $\omega$ and the attenuation coefficient $\delta$ in the high-current circuit of the HVES with CSE;

$$k_d = \exp(-\delta \omega^{-1} \arctan \delta^{-1}) \sin(\arctan \delta^{-1})^{-1}$$  
is the normalizing coefficient for a current varying in time $t$ according to the law of a damped sinusoid [14].

In the case of a change in the discharge current, $i_d(t)$ by aperiodic law having the analytical form $i_d(t) = k_d J_m \exp(-\omega \delta) \sin(\omega t)$, the calculated ratio for the action integral $J_d$ in the HVES discharge circuit with CSE will have the following view:

$$J_d = 0.5 k_d J_m \frac{2}{\alpha_1 + \alpha_2^2 - 4(\alpha_1 + \alpha_2)^{-1}},$$  
where $J_m$ is the amplitude of the unipolar pulse current $i_d(t)$ with coefficients of the temporal shape $\alpha_1$ and $\alpha_2$;

$$k_d = \left[ \frac{1}{\alpha_2} \right]^{\alpha_1 \alpha_2 - \alpha_1} \frac{(\alpha_1 / \alpha_2)^{\alpha_1 - \alpha_2}}{(\alpha_1 / \alpha_2)^{\alpha_2 - \alpha_2}}$$  
is the normalizing coefficient for the impulse current of the HVES, which varies aperiodically with time $t$ [14].

In the practical application of (3), it should be borne in mind that $\alpha_1 = 0.76/\tau_p$ and $\alpha_2 = 2.37/\tau_p$ [14], where $\tau_p$ is the duration of the aperiodic current pulse $i_d(t)$ between levels (0.1-0.9) $J_m$ and the front of the aperiodic discharge current $i_d(t)$ in the HVES discharge circuit studied under a level of 0.5 $J_m$. It is useful to find the ratio of the form $\tau = \tau_m / 1.6 = 0.625 \ln(\alpha_1 / \alpha_2 ) / (\alpha_2 - \alpha_1)$ [14] when finding the amplitude-time parameters (ATP) of the aperiodic pulse of the discharge current $i_d(t)$ of the HVES with CSE, where $\tau_m$ is the time corresponding to the $i_m$ amplitude of the unipolar current in the high-current circuit of the HVES with CSE.

With regard to the concept of the equivalent active resistance $R_c$ of the plasma channel of a spark used in (1), we mean by it a constant resistance averaged over time $t$, at which, when passing through the circuit of the HVES with CSE of the impulse discharge current $i_d(t)$, the same thermal energy, as well as on a real variable in time $t$ resistance of the plasma discharge channel in the TES of the considered HVCAS. When determining the active resistance $R_c(t)$ of the plasma channel of a spark discharge in the general form of the variable in time $t$ in the investigated switch, we use the following classical relation [14]:

$$R_c(t) = I_m / (\pi r_m^2(t) \gamma_c),$$  
where $r_c(t)$ is the radius of the plasma channel of spark discharge varying with time $t$, with constant length $l_c$ between the metal electrodes of the HVCAS; $\gamma_c$ is the averaged conductivity of low-temperature plasma in the channel of the switch spark.

The radius $r_c(t)$ of a single plasma spark channel in any design of the HVCAS varies, as is known, during the course of the impulse current $i_d(t)$ in the HVES discharge circuit with CSE in the range from zero to its maximum value $r_{cm}$ [1, 9-12]. Initially, on the increasing part of the discharge current $i_d(t)$, this change occurs from zero to $r_{cm}$, and then on the falling part of this impulse current in the HVES circuit with CSE – from $r_{cm}$ to zero. Therefore, according to (4), the time variation curve $t$ of the value of the active resistance $R_c(t)$ of the plasma spark channel in the HVCAS can be approximated by a symmetric $U$-shaped curve characterized by its two maximum values at times $t$ corresponding to zero current values $i_d(t)$ and its one minimum value at time $t$, when the current $i_d(t)$ reaches its amplitude value and $r_c = r_{cm}$. Then, taking into account the corresponding change in (4) in time $t$ of the radial function of the form $f(r) = r^2$ on the interval $[0, r_{cm}]$ and finding the average value for the equivalent and constant in time $t$ of the active resistance $R_c$ of a single plasma spark-gap channel in the investigated HVCAS, we obtain the following calculated expression:

$$R_c = l_c / (\pi r_{cm}^2 \int_{r_c}^{r_{cm}} r^2 dr_c) = 3 l_c / (\pi r_{cm}^2 \gamma_c).$$  
From (5), the proposed approach in the definition of $R_c$ implies the calculated ratio for the equivalent radius $r_{cm}$ of the plasma channel of a high-current spark in the HVCAS, equal to $r_{cm} = 0.577 r_{cm}$. The magnitude of the maximum radius $r_{cm}$ (m) of the plasma channel of a spark discharge in an atmospheric pressure HVCAS is found from the well-known Braginsky formula [1, 15]:
\[ r_{cm} = 0.093(I_m)^{1/3}(t_m)^{1/2}, \]  

where \( I_m, t_m \) are, respectively, the amplitude (A) of the pulse current \( i(t) \) in the HVES discharge circuit with powerful CSE and the time (s) corresponding to this current amplitude.

From (5) and (6), the generalized expression for the equivalent active resistance \( R_c (\Omega) \) of a single high-current plasma high-current spark discharge channel in the HVCAS placed in the HVES with CSE discharge circuit assumes the following final form:

\[ R_c = 110.41 \cdot l_{c1}/(\gamma c^{2/3} l_m). \]  

When selecting (7) for the numerical values of \( \gamma_c \) values will be based on its own computational and experimental data obtained earlier for plasma spark discharge air passage in the high-current circuit of HVES with powerful CSE [15]. According to the results of the studies presented in [15], for high-voltage atmospheric air switches at operating DC voltage up to ±35 kV and pulse currents of microsecond duration in the discharge circuit of HVCAS capacitor bank with a low resistance \( RL \)-load at their amplitude up to ±250 kA, characteristic for a pulse components artificial lightning current [16], the averaged conductivity value \( \gamma_c \) low-temperature plasma in a cylindrical channel HVCAS spark in the first approximation, taking into account (5) and (6) numerically from 4000 to 5000 (\( \Omega \)·m\(^{-1} \)). It should be noted that these values \( \gamma_c \) differ significantly from the corresponding values of the estimated temperature plasma conductivity of high spark air (about 20·10\(^3\) (\( \Omega \)·m\(^{-1} \))) is given in [1] and the characteristic of the highly ionized plasma. Let us note that, at an electron temperature in the high-current spark discharge channel of the order of 10\(^8\) K, which is characteristic of the channel of an air high-current spark in the investigated HVCAS [17], even in a dense plasma of the underwater spark discharge channel initiated by an electric explosion of a thin copper wire, the numerical values for its specific electric conductivity \( \gamma_c \) channel depending on the pressure level is not more than a few thousand (\( \Omega \)·m\(^{-1} \)) [18].

Next, we estimate the value of thermal energy \( W_e \), which is released on two massive metal electrodes of the considered HVCAS, schematically shown in Fig. 1. The determining effect on \( W_e \) will be the power density \( g_c(t) \) of the heat flux in the plasma spark channel between the cathode and the anode of the HVCAS. In the estimation of \( g_c(t) \) in the proposed approach, a relationship of the form [17] can be used:

\[ g_c(t) = \delta d(t) \cdot \frac{\gamma_c}{\omega} \cdot U_{ac}, \]  

where \( U_{ac} \) is the electrode voltage drop in the considered HVCAS, equal to the difference of electrical potentials at the interface between the «spark-metal» media.

It is known that the value of \( U_{ac} \) in the investigated HVCAS with the main electrodes made of such traditional conductor materials as steel, copper, brass and beryllium bronze varies in a very narrow quantitative range, ranging from 5 to 10 V [19]. Thus, for steel grade Cr.3, the near-electrode voltage drop \( U_{ac} \) is numerically about 6.1 V, for copper – 8.6 V, and for brass – 8.0 V [19]. Taking into account the assumed assumptions and (8) for the thermal energy \( W_e \) dissipated on the working surfaces of the metal electrodes of the TES we can write the calculated expression:

\[ W_e = 2 \pi \int_0^\infty \left[ g_c(t) \cdot \frac{\gamma_c}{\omega} \cdot U_{ac} \right] dt = 2 \pi \int_0^\infty \left[ \delta d(t) \cdot \frac{\gamma_c}{\omega} \cdot U_{ac} \right] dt = 2 U_{ac} \cdot q_c, \]  

where \( q_c = \int_0^\infty \delta d(t)dt \) – the module of the electric charge flowing through the plasma channel of the spark discharge in the high-current circuit of the HVES with powerful CSE and the metal electrodes of the investigated HVCAS.

It is seen from (9) that for the calculated determination of the thermal energy \( W_e \) we need to first know the amount of electricity \( q_c \) that has flowed through the electrodes of the HVCAS. Moreover, the desired value of \( W_e \) is directly proportional to the electric charge \( q_c \). When changing the impulse current \( i_d(t) \) in the discharge chain of HVES with SNE according to the law of an exponentially damped sinusoid, the following relation can be used to calculate the charge \( q_c \):

\[ q_c = k_{ds} \cdot l_{ms} \cdot \omega^{-2} \left[ (\delta / \omega)^2 + 1 \right]^{-1}. \]  

At changing the impulse current \( i_d(t) \) with respect to the aperiodic time dependence for \( q_c \), we have:

\[ q_c = k_{ds} \cdot l_{ms} \cdot (\alpha_2^2 - \alpha_1^2)(\alpha_1^2 - \alpha_2^2)^{-1}. \]  

One of the checks on the correctness of the calculation results for (10) and (11) for \( q_c \) is the data obtained from the expression \( q_c = C_p U_{gc} \), where \( C_p \) and \( U_{gc} \) are the electrical capacitance and charging voltage of the high-voltage capacitors of CSE, respectively.

Thus, by determining the value of the heat energy \( W_e \) dissipated in the spark channel by (1) – (3) and (7) and calculating the thermal energy by the heat energy \( W_e \) scattered at the cathode and the anode of the TES by (9) – (11), from the expression \( W_1 = W_e + W_2 \) can find the total energy release in the high-current air circuit of the HVES discharge circuit with CSE.

3. Approximate calculation of the electrical erosion of electrodes in the HVCAS of the discharge circuit of the HVES with CSE. In the framework of this study, let us dwell on the estimated estimation of the electric erosion of the working surface of the metal electrode-anode HVCAS caused by a stream of free electrons accelerating in the longitudinal electric field of
the channel, bombarding the indicated surface of the anode of the switch under consideration. In this case, for the thermal energy $W_a$, which is dissipated in the circular zone of the binding of the spark discharge channel with a radius $r_m$ on the working surface of the anode of the HVCAS, one can, on the basis of (9), write the following relationship:

$$W_a = U_{ac} q_e.$$  \hspace{1cm} (12)

On the other hand, for the sought value of the thermal energy $W_a$, based on the positions of thermal physics, the following calculated formula will hold true:

$$W_a = M_e \left[ C_e (\theta_m - \theta_0) + C_m \right],$$  \hspace{1cm} (13)

where $M_e = d_e V_e$ is the mass of intensely heated by the pulsed discharge current $i_d(t)$ in the circular binding zone on the surface of the electrode electrode-anode of the HVCAS of the spark channel to the melting point $\theta_m$ of its material having the density $d_e$ and volume $V_e; C_e, C_m$ are, respectively, the specific heat and specific heat of fusion of the anode material of the considered HVCAS.

The value of the volume $V_e$ of the melt and ejected outward by the magnetic pressure of the liquid metal of the switch, for one exposure of the spark channel to it, taking into account the assumed assumption about the geometric form of the crater of destruction on its working surface in the form of a ball segment, can be described by the following relation:

$$V_e = 0.5 \pi r_m^2 h_e,$$  \hspace{1cm} (14)

where $h_e$ is the depth of the rupture crater with an outer radius $r_m$ on the working surface of the HVCAS anode during the time of exposure to a spark from one high-current discharge of the HVES capacitor bank.

From (12) – (14), taking into account (6), the calculated expression for the maximum depth $h_e$ (m) of a single erosion crater of destruction on the electrode-anode of the switch under consideration takes the following form:

$$h_e = 73.6 U_{ac} q_e d_e^{-1} \left[ C_e (\theta_m - \theta_0) + C_m \right]^{-1} (I_m^2/r_m)^{-1}.$$  \hspace{1cm} (15)

For the reduce the mass $M_e$ (kg) of metal emitted outward by a high-current spark from the anode electrode for one spark discharge in the HVES circuit with CSE and the working air gap of the HVCAS in question, we obtain the following calculated ratio:

$$M_e = U_{ac} q_e C_e (\theta_m - \theta_0) + C_m \right].$$  \hspace{1cm} (16)

It follows from (16) that the calculated loss of the metal mass $M_e$ from the electrode-anode of the investigated switch for one discharge of powerful CSE in the HVES circuit is directly proportional to the charge $q_e$ that has flowed through the main electrodes of the HVCAS. Note that such dependence for $M_e$ was previously established experimentally for commutation in the HVES discharge circuit with CSE of large pulsed exponentially decaying sinusoidal currents of microsecond duration for copper, molybdenum and titanium electrodes of the HVCAS [20]. In the first approximation, for the loss of the $M_e$ mass due to the anode electrode of the switch for $N$ spark discharges of the powerful CSE of the electrophysical unit through the HVCAS, one can use the calculated ratio of the form: $M_e = N M_e$. In addition, we point out that when calculating the electrical erosion of the metal electrode-cathode of the HVCAS, the calculated expressions (15) and (16) can be used.

4. Experimental verification of the results of calculating the electrical erosion of steel electrodes in the HVCAS discharge circuit of the HVES with ENE. This test was performed in the HVES discharge circuit with a powerful single-module CSE for a rated voltage of ±50 kV with nominal power capacity of its capacitor bank $W_{0g} = 416$ kJ (111 pieces of parallel-connected high-voltage capacitors of the type HK-50-3) forming on the concentrated RL-load ($R_l \approx 10 \, \Omega, L_2 \approx 0.3 \, \mu F$) of microsecond duration [9, 14]. We will point out that the experimental HVES had the following electric parameters (up to the prefabricated steel buses of the CSE collector without taking into account the influence of the switch) [9, 14]: capacitance $C_p = 333 \, \mu F$; inductance $L_2 = 2.05 \, \mu H$; active resistance $R_l \approx 57 \, \Omega$. To switch the energy used by the HVES to the CSE a cascade-type HVCAS was used for a rated voltage of ±50 kV, containing two main massive hemispherical electrodes of radius $R_e \approx 61.5 \, mm$ and one controlling a massive spherical electrode 30 mm in diameter made of steel of grade Cr.3 (Fig. 2) [7, 9].

**Fig. 2.** Enlarged view of a three-electrode system of the cascade type HVCAS with two hemispherical massive main electrodes and one control electrode of a spherical steel Cr.3 marks on the rated voltage ±50 kV and a pulse microsecond current amplitude $I_m$ up to ±300 kA (type after a single exposure at its electrodes in steel HVES discharge circuit with powerful pulse CSE damped sinusoidal current frequency $\omega = 4.9$ kHz and amplitude of the first $I_{0m} = 202 \, kA; J_p = 2.12 \times 10^6 \, A/\Omega$; experimental channel radius value sparks $r_{ch} = 31 \, mm$ length channel spark $l_w = 13.5 \, mm$).

At the charging voltage of high-voltage impulse capacitors of this CSE is equal to $U_{ac} = 29.7 \, kV$ and the energy stored in them is $W_e = 147 \, kJ$, the working air gap between the control electrode of the HVCAS and its
potential main electrode is \( l_{1}=9 \) mm, and from the non-potential side The main electrode of the switch, the working air gap was \( l_{2}=4.5 \) mm. In this connection, in the experimental HVCAS, the length of the high-current spark was approximately \( l_{c} = l_{1} + l_{2} = 13.5 \) mm. After a high voltage igniting microsecond voltage pulse of amplitude of \( \pm 100 \) kV (its polarity corresponded to the charge polarity of the CSE capacitors) was applied to the control electrode of the HVCAS from a special generator [7, 9], an electrical breakdown of an air gap of length \( l_{2} \) occurred, which resulted in the breakdown of an air gap of length \( l_{c} \) and trip mentioned switch as a whole. As a result of triggering HVCAS between its steel electrodes a high-current air spark appeared, which destroys the working surfaces of the anode, cathode and control electrode of the switch. In Fig. 2 the results of such electrothermal action on these steel electrodes of the high-current plasma channel of an air spark discharge occurring in the HVCAS of the experimental HVES (\( U_{ge} = -29.7 \) kV) are shown, in the case of LIC flowing through them, whose oscillogram is shown in Fig. 3.

According to the diagram in Fig. 3 the oscillogram of the damped sinusoidal LIC \( i_{d}(t) \) with the first half-wave of negative polarity in the discharge circuit of the HVES of its ATP at the total duration of the current pulse \( t_{p}=500 \) \( \mu \)s was approximately equal in absolute value: \( I_{m}=202 \) kA; \( \omega = 13.00 \cdot 10^{3} \) s\(^{-1}\); \( \delta_{C}=30.79 \cdot 10^{3} \) s\(^{-1}\); \( k_{ds}=1.783 \); \( t_{ms}=36 \) \( \mu \)s; \( t_{ms}=6.1 \) V; \( d_{a}=7870 \) kg/m\(^3\); \( C_{M}=460 \) J/(kg·\( ^\circ \)C); \( C_{m}=84 \cdot 10^{3} \) J/kg; \( \delta_{0}=0^\circ \); \( \theta_{e}=1500^\circ \) \([8, 10]\) we find that in our case the calculated maximum depth \( h_{e} \) for erosion craters of failure at their design radius \( r_{cm}=32.7 \) mm on the working surfaces of the main steel electrodes of HVCAS when flowing through the switchboard in a single pulse discharge of a powerful CSE (\( U_{ge} = -29.7 \) kV; \( W_{g}=147 \) kJ) in the high-current circuit of the experimental WEFU electric charge \( q_{c}=9.93 \) C will be approximately 5.9 \( \mu \)m. As we can see, the discrepancy between the calculated and experimental values for \( h_{e} \) with respect to the HVCAS used is no more than 16\%.

We will point out that in this case the calculated loss of the metal mass \( M_{e} \) from the working surface of the steel electrode-anode in accordance with (16) is approximately 78.2 mg. Then, for the specific electric erosion of \( M_{e}/q_{c} \) of the steel electrode-anode of the considered HVCAS, we obtain a numerical value equal to about 7.8 \( \cdot 10^{-4} \) g/C. To compare this specific electroerosion wear \( M_{e}/q_{c} \) of the massive steel main
electrodes of the investigated HVCAS with known similar electrophysical data, we note that in high-current high-voltage gas-discharge switches for nominal voltage of ±50 kV type PTV1-50-100 with the main electrodes from the metal composition «tungsten-copper», designed for commutation of damped sinusoidal microsecond LIC with duration \( t_{\text{d}} \leq 100 \, \mu\text{s} \) and an amplitude of \( I_{\text{rms}} \) up to 100 kA, a specific electroerosive wear of their composite anode and a cathode But is almost two orders of magnitude smaller numerical value and is approximately \( 4.4 \times 10^{-5} \, \text{g/C} \) [21].

Conclusions.
1. In accordance with the proposed new engineering approach to approximate calculated energy estimates and electrical erosion in large metal electrodes in the HVCAS of atmospheric pressure, performing switching in a discharge circuit of the HVES with powerful CSE, only necessary data on the electrical and thermal characteristics of the anode metal and its cathode TES averaged conductivity \( \gamma_c \) of low-temperature plasma in a channel of the air spark discharge between the electrodes of the HVCAS ATP of pulsed discharge current \( i(t) \) in high-current circuit of the HVES with CSE.
2. It has been established that when calculating the thermal energy \( W \), that is dissipated in the air spark of the investigated HVCAS, a new electrophysical concept concerning the equivalent active resistance \( R_e \) of a pulsed air spark that is constant during the whole process of oscillating or aperiodic discharge of the CSE of the HVES on the electric load can be used. The original calculation formula (7) is obtained to find the approximate numerical value of \( R_e \) from the known data for \( \gamma_c \), the length \( l \), of the air spark channel, and the ATP of pulsed sinusoidal (aperiodic) discharge current of the CSE in the high-current HVES circuit on the RL-load.
3. The performed high-current experiments in the HVES discharge circuit with powerful CSE confirmed the reliability of certain obtained and used formulas calculation relations (in particular, formulas (6), (10), (15) and (16)) for approximate estimation of energy dissipation and electric erosion of massive metal electrodes of TES in the investigated HVCAS of atmospheric pressure.
